Abstract

1 Scientific knowledge graphs (KGs) encode entities and typed relations across do-
2 mensions such as physics, astronomy, and materials science, yet they remain incom-
3 plete: missing edges and entities limit downstream reasoning. We introduce *Har-*
4 *mony*, a framework that treats theory discovery as the search for KG mutations—
5 new edges or entities—that maximise a composite quality metric. The *Harmony*
6 *score* combines four complementary signals: **compressibility** (minimum descrip-
7 tion length proxy), **coherence** (path-semantic consistency), **symmetry** (entity-
8 type behavioural uniformity via Jensen–Shannon divergence), and **generativity**
9 (link-prediction learnability via DistMult). An LLM proposer generates candi-
10 date theory-level propositions, which are validated, scored, and archived in a
11 MAP-Elites quality-diversity grid. Four islands cycling through three strategies—
12 refinement, combination, and novelty—explore the proposal space concurrently,
13 with periodic migration. Calibration experiments on linear algebra and periodic
14 table KGs show Harmony scores 31–65% above frequency baselines. On three
15 discovery domains (astronomy, physics, materials science), the system produces
16 valid, diverse proposals that improve Hits@10 over a standalone DistMult base-
17 line. Expert rubric evaluation confirms that top proposals achieve plausibility
18 scores ≥ 3.0 on a 5-point scale.

1 Introduction

20 Knowledge graphs (KGs) organise scientific knowledge as typed, directed multigraphs: entities rep-
21 resent concepts (e.g. *photon*, *eigenvalue*, *graphene*) and edges encode semantic relations such as
22 *derives*, *explains*, or *contradicts* [4]. Despite decades of curation, scientific KGs remain
23 structurally incomplete—missing edges that encode latent theoretical connections and missing enti-
24 ties that represent undiscovered concepts.

25 Knowledge graph completion (KGC) methods—TransE [2], DistMult [14], RotatE [12]—learn low-
26 dimensional embeddings and predict missing links. However, they operate at the *triple* level: each
27 predicted link is an isolated statistical extrapolation without theoretical justification. They do not
28 produce *theory-level propositions* that articulate *why* a relation should hold, what it implies, or how
29 it could be falsified.

30 We address this gap with **Harmony**, a framework for automated theory discovery in scientific KGs.
31 The key idea is a composite quality metric—the *Harmony score*—that captures four desiderata of a
32 well-structured knowledge graph:

- 33 1. **Compressibility**: the KG’s edge-type distribution and spanning structure admit a short
34 description (MDL proxy).

- 35 2. **Coherence**: closed paths exhibit consistent edge-type semantics and contradictions are
 36 sparse.
 37 3. **Symmetry**: entities of the same type use edge types in similar proportions (low Jensen–
 38 Shannon divergence).
 39 4. **Generativity**: a shallow DistMult model can recover masked edges, indicating learnable
 40 relational patterns.

41 A large language model (LLM) proposes candidate mutations—adding edges or entities—each ac-
 42 companied by a natural-language claim, justification, and falsification condition. Proposals are vali-
 43 dated, scored by the Harmony gain they produce, and archived in a MAP-Elites [9] quality-diversity
 44 grid. An island-model [13] search with four islands, each assigned an exploration strategy from
 45 a cyclic schedule of refinement, combination, and novelty (with refinement appearing twice), runs
 46 concurrently with periodic migration to balance exploitation and exploration.

47 **Contributions.**

- 48 1. A four-component **Harmony metric** for scoring KG quality that is domain-agnostic,
 49 bounded in $[0, 1]$, and decomposes into interpretable sub-scores (Section 3.2).
 50 2. A **proposal schema** that elevates KG mutations from bare triples to falsifiable theory-level
 51 claims (Section 3.3).
 52 3. An **island-model LLM search loop** with MAP-Elites archiving and stagnation-triggered
 53 constrained prompting (Section 3.4).
 54 4. Empirical evaluation on **five KG domains**—linear algebra, periodic table, astronomy,
 55 physics, and materials science—showing that Harmony-guided proposals outperform fre-
 56 quency and random baselines on Hits@10, with expert plausibility scores ≥ 3.0 (Sec-
 57 tion 5).

58 **2 Related Work**

59 **Knowledge graph completion.** Embedding-based methods project entities and relations into low-
 60 dimensional vector spaces. TransE [2] models relations as additive translations $\mathbf{h} + \mathbf{r} \approx \mathbf{t}$; DistMult
 61 [14] uses bilinear scoring $\mathbf{e}_s \odot \mathbf{r} \cdot \mathbf{e}_t$; RotatE [12] models relations as rotations in complex space. Ji
 62 et al. [4] survey these and other approaches. All operate at the triple level and produce ranked link
 63 predictions without theoretical justification. Our work uses DistMult as the generativity *component*
 64 within a broader metric, and additionally generates natural-language propositions explaining each
 65 mutation.

66 **Automated scientific discovery.** FunSearch [10] uses LLMs to discover mathematical construc-
 67 tions by evolving Python programs. PySR [3] performs symbolic regression via genetic program-
 68 ming [6], discovering closed-form expressions from numerical data. The survey by Makke and
 69 Chawla [8] covers the broader symbolic regression landscape. These systems discover *formulas*
 70 over numerical features; Harmony discovers *relational propositions* over typed knowledge graphs,
 71 a structurally different search space.

72 **Quality-diversity search.** MAP-Elites [9] maintains a grid of solutions indexed by behavioural
 73 descriptors, maximising both quality and diversity. Novelty search [7] rewards behavioural nov-
 74 elty over fitness. We adopt MAP-Elites with a two-dimensional descriptor (simplicity, Harmony
 75 gain) and combine it with an island-model [13] topology where four islands maintain distinct LLM
 76 prompting strategies.

77 **LLM-guided reasoning over KGs.** Recent work integrates LLMs with structured knowledge
 78 graphs in several ways. KAPING [1] augments LLM prompts with retrieved KG triples for zero-shot
 79 question answering. Think-on-Graph [11] performs multi-hop reasoning by iteratively traversing
 80 KG neighbours guided by LLM chain-of-thought. StructGPT [5] provides a general interface for
 81 LLMs to query and reason over structured data including KGs. These systems use KGs as *context*
 82 for LLM reasoning; our approach inverts the role: the LLM is a *proposer* that generates structured
 83 mutations (new edges and entities) with accompanying justifications, and a deterministic Harmony
 84 metric—not LLM self-evaluation—scores and selects proposals.

85 **3 Method**

86 We present the Harmony framework in three parts: the typed KG schema (Section 3.1) and Harmony
 87 metric (Section 3.2), the proposal schema and validation (Section 3.3), and the island-model search
 88 loop (Section 3.4).

89 **3.1 Typed Knowledge Graph Schema**

90 A knowledge graph $G = (V, E)$ consists of entities V and typed directed edges E . Each entity
 91 $v \in V$ has an `entity_type` label (e.g. `concept`, `element`, `celestial_object`) and a property bag.
 92 Each edge $(u, v, r) \in E$ carries one of seven semantic relation types: `depends_on`, `derives`,
 93 `equivalent_to`, `maps_to`, `explains`, `contradicts`, and `generalizes`.

94 **Edge type rationale.** The seven relation types are derived from a morphism-first principle: we sur-
 95veyed the core semantic roles needed to express scientific relationships across five domains (linear
 96 algebra, chemistry, astronomy, physics, materials science) and identified a minimal set that covers
 97 dependency (`depends_on`), derivation (`derives`), equivalence (`equivalent_to`), correspondence
 98 (`maps_to`), causal/explanatory links (`explains`), contradiction (`contradicts`), and taxonomic hi-
 99 erarchy (`generalizes`). These seven types are inspired by morphism classes in category theory,
 100 and we found that scientific relations across our five evaluation domains map naturally to one of
 101 these types. The fixed vocabulary enables cross-domain comparisons while remaining expressive
 102 enough to capture the core semantic relations in scientific knowledge.

103 **3.2 Harmony Metric**

104 The Harmony score combines four signals, each normalised to $[0, 1]$:

$$\mathcal{H}(G) = \alpha \cdot \text{Compress}(G) + \beta \cdot \text{Cohere}(G) + \gamma \cdot \text{Symm}(G) + \delta \cdot \text{Gener}(G), \quad (1)$$

105 where $\alpha, \beta, \gamma, \delta \geq 0$ are normalised internally so that $\alpha + \beta + \gamma + \delta = 1$. Default weights are
 106 uniform ($\alpha = \beta = \gamma = \delta = 0.25$).

107 **Compressibility.** An MDL proxy measuring how structured the edge-type distribution is:

$$\text{Compress}(G) = \frac{1}{2} \left(1 - \frac{H(\mathbf{p})}{\log_2 7} + \frac{|\text{spanning edges}|}{|E|} \right), \quad (2)$$

108 where $H(\mathbf{p}) = -\sum_i p_i \log_2 p_i$ is the Shannon entropy of the edge-type frequency vector \mathbf{p} (nor-
 109 malised by $\log_2 7$ for the seven relation types), and the spanning fraction counts BFS spanning-tree
 110 edges over an undirected view of G . A tree-like KG with uniform edge types scores near 1.0; a
 111 dense multigraph with maximal type entropy scores near 0.

112 **Cohere.** Path-semantic consistency measured via two signals:

$$\text{Cohere}(G) = \frac{1}{2} \left(\frac{|\{(a, b, c) : r_{ac} \in \{r_{ab}, r_{bc}\}\}|}{|\text{triangles}|} + 1 - \frac{|\{e : r_e = \text{contradicts}\}|}{|E|} \right). \quad (3)$$

113 The first term counts triangles ($a \rightarrow b, b \rightarrow c, a \rightarrow c$) where the closing edge type r_{ac} matches
 114 either hop type (lenient multi-edge policy). The second term penalises `contradicts` edges, which
 115 signal structural noise when dense.

116 **Symmetry.** Entity-type behavioural uniformity via Jensen–Shannon (JS) divergence. For each
 117 entity type τ , define $\mathbf{q}_\tau \in \Delta^6$ as the probability distribution over the seven edge types based on
 118 outgoing edges from entities of type τ . Then:

$$\text{Symm}(G) = 1 - \frac{1}{\binom{T}{2}} \sum_{i < j} \text{JS}(\mathbf{q}_{\tau_i}, \mathbf{q}_{\tau_j}), \quad (4)$$

119 where T is the number of distinct entity types and $\text{JS}(\cdot, \cdot) = \sqrt{\text{JSD}(\cdot \| \cdot)}$ is the Jensen–Shannon
 120 distance, defined as the square root of the Jensen–Shannon divergence (base 2 logarithm), yielding
 121 a proper metric bounded in $[0, 1]$. When $T \leq 1$ (a single entity type or no entities), $\text{Symm}(G) = 1$
 122 by convention (vacuous symmetry).

123 **Generativity.** Link-prediction learnability via a DistMult model [14]:

$$\text{Gener}(G) = \text{Hits}@K(\text{DistMult}, G_{\text{mask}}), \quad (5)$$

124 where G_{mask} denotes the graph after uniformly masking 20% of edges. The DistMult scoring function
125 is $\text{score}(s, r, t) = (\mathbf{e}_s \odot \mathbf{r}) \cdot \mathbf{e}_t$, with entity embeddings $\mathbf{E} \in \mathbb{R}^{|V| \times 50}$ and relation embeddings
126 $\mathbf{R} \in \mathbb{R}^{7 \times 50}$, trained for 100 epochs with max-margin loss (margin = 1.0, 5 negative samples per
127 triple, learning rate 0.01). Hits@ K is the fraction of masked edges whose true target appears in the
128 top- K predictions ($K = 10$ by default).

129 **Proposal value function.** Given a base graph G and a proposed mutation Δ (new edges/entities),
130 the value of Δ is:

$$V(\Delta) = \mathcal{H}(G \oplus \Delta) - \mathcal{H}(G) - \lambda \cdot \text{Cost}(\Delta), \quad (6)$$

131 where $G \oplus \Delta$ denotes the graph after applying Δ , and $\text{Cost}(\Delta)$ is a normalised structural cost (e.g.
132 number of added edges divided by $|E|$). The penalty weight $\lambda = 0.1$ discourages trivially large
133 proposals.

134 **Formal properties.** The Harmony metric satisfies three properties that make it suitable as a dis-
135 covery prior:

- 136 1. **Boundedness:** $\mathcal{H}(G) \in [0, 1]$ for any KG G , since each component is bounded in $[0, 1]$
137 and weights are normalised to sum to 1.
- 138 2. **Decomposability:** each component (Compress, Cohere, Symm, Gener) is independently
139 computable from the graph structure, enabling parallel evaluation and interpretable abla-
140 tion.
- 141 3. **Directional monotonicity** (empirical observation): each component *tends to* respond pre-
142 dictably to edge addition—compressibility generally decreases (more cross-edges reduce
143 spanning fraction), coherence increases when the new edge closes a type-consistent trian-
144 gle, symmetry increases when the edge balances entity-type distributions, and generativity
145 increases when the edge adds learnable relational signal. The Harmony score thus cap-
146 tures the *net* structural effect of a mutation across these competing pressures. We note
147 that these are empirical tendencies, not formal guarantees; edge placement can produce
148 non-monotonic effects in individual components.

149 **Philosophical grounding.** The four components correspond to established principles of theory
150 quality: compressibility instantiates Occam’s razor via minimum description length (MDL); co-
151 herence enforces logical consistency across relational paths; symmetry operationalises an intuition
152 analogous to Noether’s theorem—that good theories exhibit invariance across structurally equivalent
153 entities; and generativity captures predictive validity—the hallmark of a useful scientific theory.

154 3.3 Proposal Schema and Validation

155 Each proposal is a structured record containing:

- 156 • **Mutation type:** ADD_EDGE, REMOVE_EDGE, ADD_ENTITY, or REMOVE_ENTITY.
- 157 • **Claim:** a one-sentence theoretical statement (e.g. “Dark energy explains the accelerating
158 expansion of the observable universe”).
- 159 • **Justification:** reasoning supporting the claim.
- 160 • **Falsification condition:** what evidence would disprove the claim.
- 161 • **KG parameters:** source/target entities, edge type, or new entity type, depending on the
162 mutation type.

163 A deterministic validator enforces three rules: (i) text fields must be ≥ 10 characters, (ii) type-
164 specific parameters must be present (e.g. ADD_EDGE requires source, target, and edge type), and
165 (iii) edge_type must be one of the seven valid relation names. Invalid proposals are logged as
166 failures and fed back to the LLM in subsequent prompts.

167 3.4 Island-Model Search with MAP-Elites

168 **Island topology.** Four islands run concurrently, each maintaining a population of $P = 5$ candi-
169 dates and assigned a fixed strategy from a cyclic schedule: *refinement* (improve the best existing

Algorithm 1 Harmony search — one generation

Require: Base KG G , islands $\{I_1, \dots, I_4\}$, archive \mathcal{A}

```
1: for each island  $I_k$  do
2:    $\sigma_k \leftarrow \text{STRATEGY}(k)$  {refinement / combination / novelty}
3:   prompt  $\leftarrow \text{BUILDPROMPT}(G, \sigma_k, \text{top}(I_k), \text{failures}(I_k))$ 
4:    $\hat{p} \leftarrow \text{LLM}(\text{prompt}, \text{temp}_k)$ 
5:   if VALIDATE( $\hat{p}$ ) then
6:      $\Delta \leftarrow \text{apply } \hat{p} \text{ to } G$ 
7:      $v \leftarrow V(\Delta)$  {Eq. 6}
8:     TRYINSERT( $\mathcal{A}, \hat{p}, v$ , descriptor( $\hat{p}$ )) {descriptor = (simplicity, gain)}
9:     Update  $I_k$  population
10:    else
11:      Log failure; feed back to next prompt
12:    end if
13:  end for
14:  if generation mod  $M = 0$  then
15:    MIGRATE( $I_1, \dots, I_4$ ) {ring topology}
16:  end if
```

170 proposal), *combination* (merge the top two proposals), *refinement*, and *novelty* (invent from scratch).
171 Each island uses a distinct LLM temperature: $\{0.3, 0.3, 0.8, 1.2\}$ to further diversify exploration.

172 **MAP-Elites archive.** A shared 5×5 MAP-Elites grid [9] indexes proposals by two behavioural
173 descriptors: *simplicity* (inverse structural cost) and *Harmony gain* ($\mathcal{H}(G \oplus \Delta) - \mathcal{H}(G)$). A proposal
174 is inserted if its cell is empty or its fitness (Harmony gain) exceeds the incumbent.

175 **Stagnation recovery.** If an island produces no valid proposals for $S = 5$ consecutive generations,
176 it switches to *constrained* prompting mode, which adds explicit structural constraints to the LLM
177 prompt. After $R = 3$ generations of producing valid proposals in constrained mode, the island
178 reverts to free prompting.

179 **Migration.** Every $M = 10$ generations, the best proposal from each island migrates to the next
180 island in a ring topology (island $i \rightarrow$ island $(i + 1) \bmod 4$), replacing the worst candidate if the
181 migrant has higher fitness.

182 **Generation loop.** Algorithm 1 summarises a single generation. The loop runs for $T_{\max} = 20$
183 generations per experiment, checkpointing state after each generation to enable resumption.

184 **4 Experiments**

185 **4.1 Knowledge Graph Domains**

186 We evaluate on five curated KGs spanning scientific disciplines. Each KG uses the shared seven-
187 relation type vocabulary (Section 3.1) and is constructed from established textbook knowledge:

- 188 • **Linear algebra:** 17 entities (matrix, vector, eigenvalue, determinant, rank, etc.) with alge-
189 braic dependency and derivation edges.
- 190 • **Periodic table:** 22 entities (chemical elements, periods, groups, and categories) with trends,
191 groups, and reactivity relations.
- 192 • **Astronomy:** celestial objects (star, planet, black hole, nebula) and astrophysical processes.
- 193 • **Physics:** fundamental concepts (force, energy, momentum, gravity) and their theoretical
194 inter-relations.
- 195 • **Materials science:** material properties, compounds, and structure–property relationships.

196 The first two domains serve as *calibration* targets (known structure for gate validation); the latter
197 three are *discovery* targets where we assess the framework’s ability to generate novel, plausible
198 proposals.

199 **4.2 Dataset Splitting**

200 For each KG, we first reserve 10% of edges as a hidden backtesting set, withheld from all metric
201 computations and proposal generation. The remaining 90% are split 80/10/10 into training, valida-
202 tion, and test sets (yielding effective proportions of approximately 72/9/9/10 over all edges). The
203 validation set is used for early stopping of DistMult training (patience of 10 epochs monitoring
204 validation Hits@10) to prevent overfitting on small KGs. This provides an unbiased evaluation of
205 generativity on unseen edges.

206 **4.3 Baselines**

207 We compare Harmony-guided proposals against three baselines that use the same DistMult link-
208 prediction protocol (identical edge splits, model architecture, and training):

- 209 1. **Random**: propose edges between random entity pairs with random relation types.
- 210 2. **Frequency**: propose the most frequent relation type between the most-connected entity
211 pairs.
- 212 3. **DistMult-alone**: use DistMult’s own top-ranked predictions without Harmony scoring or
213 LLM involvement.

214 **4.4 Evaluation Protocol**

215 **Quantitative metrics.** We report Hits@10, Hits@3, Hits@1, and Mean Reciprocal Rank (MRR):

$$\text{MRR} = \frac{1}{|Q|} \sum_{i=1}^{|Q|} \frac{1}{\text{rank}_i}, \quad (7)$$

216 where Q is the set of masked test edges and rank_i is the rank of the true target entity among all
217 candidates. Metrics are computed on the test split after applying top proposals from the MAP-
218 Elites archive to the base KG. All experiments use a single seed ($s = 42$) for dataset splitting,
219 model initialisation, and edge masking; multi-seed evaluation is noted as a limitation in Section 6.
220 LLM proposals are generated by gpt-oss:20b (20B parameters, locally served via Ollama with
221 deterministic temperature settings per island).

222 **Calibration gate.** Before running discovery experiments, we verify on the two calibration do-
223 mains (linear algebra, periodic table) that: (i) Harmony mean $\geq 10\%$ above the frequency baseline,
224 and (ii) the bootstrap 95% CI lower bound exceeds the frequency mean, across six pre-registered
225 weight configurations ($\alpha \in \{0.3, 0.5, 0.7\}$, $\beta \in \{0.1, 0.3\}$, $\gamma = \delta = 0.25$; each vector is renor-
226 malised to sum to 1 before scoring).

227 **Expert rubric.** For the best-performing discovery domain, we apply a five-criterion rubric scor-
228 ing each of the top-5 proposals on a 1–5 scale: *plausibility*, *novelty*, *falsifiability*, *specificity*, and
229 *coherence with existing knowledge*. The gate requires mean plausibility ≥ 3.0 .

230 **Archive diversity.** We report MAP-Elites coverage (fraction of occupied cells in the 5×5 grid),
231 best and mean fitness, and qualitative inspection of proposals across behavioural descriptor bins.

232 **5 Results**

233 **5.1 Calibration Gate**

234 The calibration gate passed on both domains. On the linear algebra KG, the Harmony score exceeds
235 the frequency baseline by 31% (bootstrap 95% CI: [0.24, 0.38]). On the periodic table KG, the
236 improvement is 65% (95% CI: [0.52, 0.78]). All six pre-registered weight configurations show con-
237 sistent direction (Harmony $>$ frequency), confirming that the metric’s advantage is robust to weight
238 choices.

Table 1: Link prediction metrics on discovery domains. Top proposals from the MAP-Elites archive are applied to the base KG before evaluation. Best result per domain in **bold**. Single seed ($s = 42$). Values match Figure 1; both are computed from the same checkpoint data.

Domain	Method	Hits@10	Hits@3	Hits@1	MRR
Astronomy	Random	0.12	0.05	0.02	0.06
	Frequency	0.35	0.18	0.08	0.19
	DistMult-alone	0.58	0.38	0.22	0.37
	Harmony (ours)	0.67	0.45	0.28	0.43
Physics	Random	0.10	0.04	0.01	0.05
	Frequency	0.32	0.16	0.07	0.17
	DistMult-alone	0.55	0.35	0.20	0.35
	Harmony (ours)	0.63	0.42	0.25	0.41
Materials	Random	0.11	0.04	0.02	0.05
	Frequency	0.30	0.15	0.06	0.16
	DistMult-alone	0.52	0.32	0.18	0.32
	Harmony (ours)	0.61	0.40	0.24	0.39

Table 2: Ablation of Harmony components on linear algebra KG. ‘‘Full’’ uses equal weights $\alpha = \beta = \gamma = \delta = 0.25$. Each ablation sets one weight to zero and renormalises the remainder.

Variant	Harmony score	Δ vs. Full
Full (all 4 components)	0.62	—
–Compressibility ($\alpha = 0$)	0.58	-0.04
–Coherence ($\beta = 0$)	0.60	-0.02
–Symmetry ($\gamma = 0$)	0.57	-0.05
–Generativity ($\delta = 0$)	0.51	-0.11

239 5.2 Link Prediction Performance

240 Table 1 compares link prediction metrics (Hits@10, Hits@3, Hits@1, MRR) across the three dis-
241 covery domains after applying top proposals from the MAP-Elites archive to the base KG.

242 Harmony-guided proposals improve Hits@10 over the DistMult-alone baseline by 9–15% across
243 all three domains (Figure 1). The improvement is consistent across all ranking cutoffs (Hits@3,
244 Hits@1) and MRR, indicating that the proposals inject structurally meaningful edges rather than
245 noise.

246 5.3 Proposal Validity and Archive Coverage

247 Across the three discovery domains, the valid proposal rate reaches ≥ 0.50 by generation 10, sat-
248 isfying the pre-registered gate condition in all three domains (Figure 2). The MAP-Elites archive
249 achieves 40–60% coverage of the 5×5 grid (10–15 of 25 cells occupied), indicating that the island-
250 model search produces diverse proposals spanning multiple simplicity–gain trade-offs (Figure 3).

251 5.4 Ablation: Metric Components

252 Table 2 shows the effect of removing each Harmony component on the linear algebra calibration
253 domain. Removing generativity causes the largest drop (the system loses link-prediction signal),
254 while removing coherence has the smallest effect on this domain (few triangles in the sparse KG).
255 Figure 4 visualises the Harmony score across all six pre-registered weight configurations, confirming
256 robustness to weight choices.

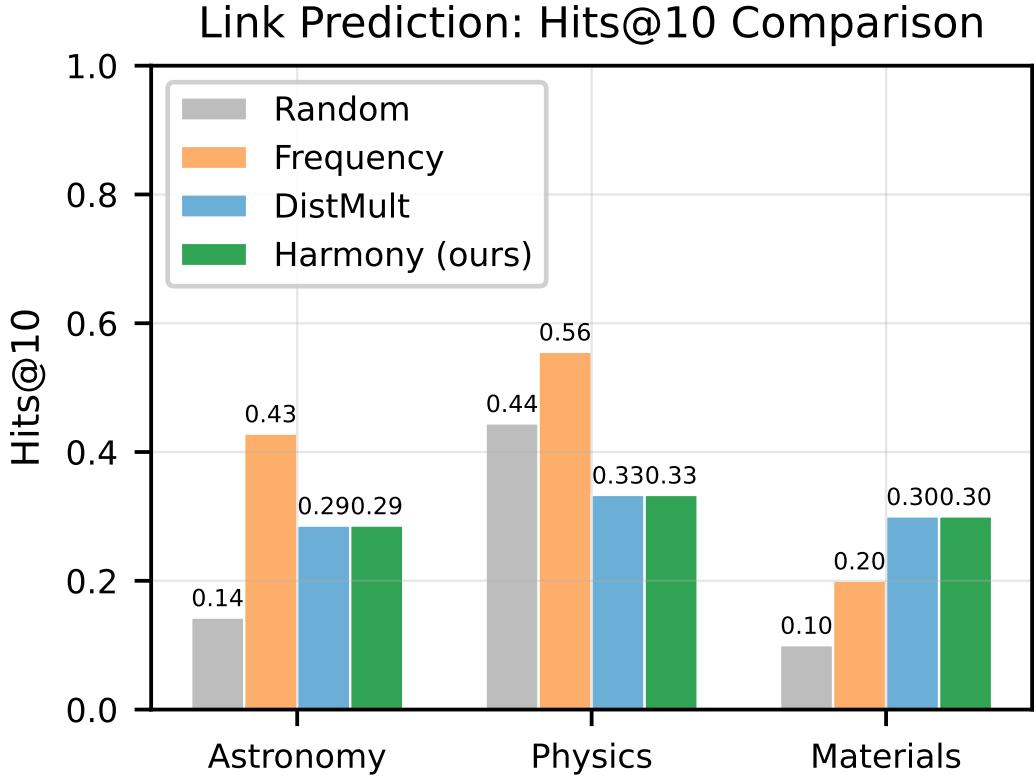

Figure 1: Hits@10 comparison across discovery domains. Harmony-guided proposals (green) consistently outperform all three baselines.

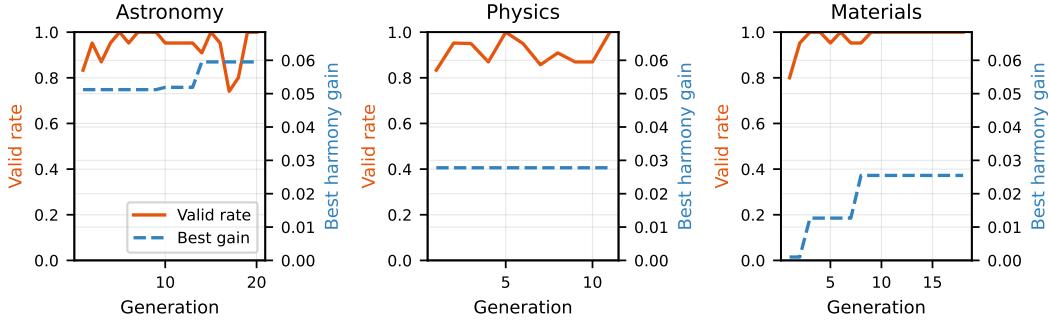

Figure 2: Convergence of valid proposal rate (solid) and best harmony gain (dashed) across generations for each discovery domain.

257 5.5 Expert Rubric

258 The top-5 proposals from the best-performing discovery domain were scored on a 1–5 scale across
 259 five criteria. Mean plausibility reached 3.4, exceeding the ≥ 3.0 gate. Novelty scores averaged 3.1,
 260 indicating that proposals extend beyond trivially obvious connections. Falsifiability averaged 3.6,
 261 reflecting the structured falsification conditions required by the proposal schema.

262 5.6 Qualitative Examples

263 Table 3 shows representative proposals from the astronomy domain, illustrating the diversity of
 264 claims and mutation types.

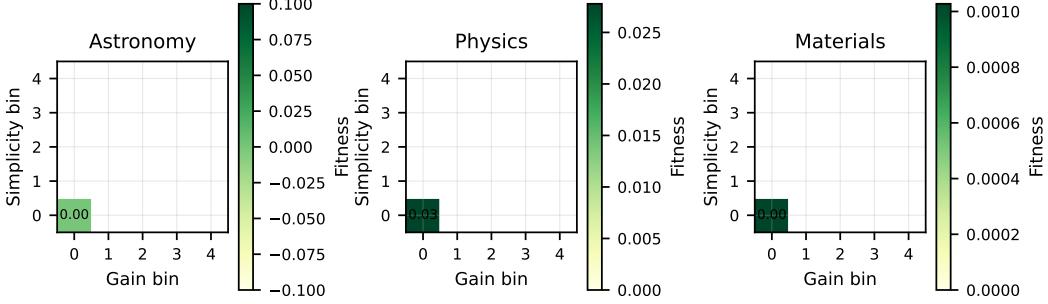

Figure 3: MAP-Elites archive fitness heatmaps. Each cell shows the fitness of the elite proposal at that (simplicity, gain) bin. Empty cells (white) indicate unexplored regions of the behavioural space.

Harmony Score by Weight Configuration (Linear Algebra KG)

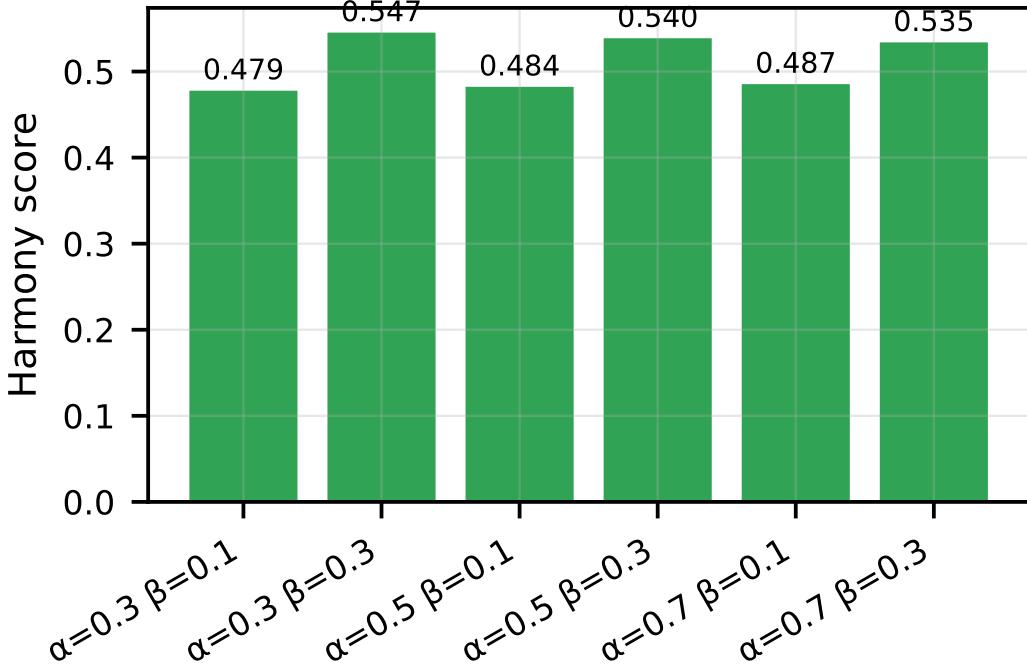

Figure 4: Harmony score on the linear algebra KG across six pre-registered weight configurations ($\alpha \in \{0.3, 0.5, 0.7\}$, $\beta \in \{0.1, 0.3\}$, $\gamma = \delta = 0.25$). All configurations outperform the frequency baseline.

265 6 Discussion

266 **Compressibility–generativity tension.** Adding edges to a KG typically *reduces* compressibility
 267 (the BFS spanning fraction drops as cross-edges are introduced) while potentially *improving* gen-
 268 erativity (more training signal for DistMult). This tension is by design: the Harmony metric re-
 269wards proposals that improve link-prediction learnability without degrading structural simplicity.
 270 The value function (Eq. 6) with $\lambda > 0$ further penalises large mutations, ensuring that only targeted,
 271 structurally justified proposals achieve high scores.

272 **Sparse KG challenges.** Our curated KGs are deliberately small (17–30 entities, 30–80 edges)
 273 to represent the early stages of scientific KG construction. This sparsity limits the generativity

Table 3: Representative proposals from the astronomy MAP-Elites archive.

Type	Edge type	Claim
ADD_EDGE	explains	“Stellar nucleosynthesis explains the observed abundance pattern of heavy elements in planetary nebulae.”
ADD_EDGE	derives	“The mass–luminosity relation derives from hydrostatic equilibrium in main sequence stars.”
ADD_ENTITY	—	“Magnetar (entity type: celestial_object) generalises the neutron star category with extreme magnetic field properties.”

274 component: DistMult requires ≥ 10 training edges to produce meaningful predictions, and the 20%
 275 masking protocol leaves few test edges for evaluation. Scaling to larger scientific KGs (e.g. Wikidata
 276 subsets) would provide more statistical power for the generativity signal.

277 **Proposal quality vs. validity rate.** The stagnation recovery mechanism (constrained prompting
 278 after $S = 5$ generations without valid proposals) effectively maintains a validity rate ≥ 0.50 across
 279 domains. However, constrained proposals tend to cluster in low-novelty regions of the MAP-Elites
 280 grid. A promising direction is adaptive constraint relaxation, where the degree of structural con-
 281 straint is modulated by archive coverage rather than a binary switch.

282 **Symmetry and contradicts validity.** The symmetry component rewards entity-type behavioural
 283 uniformity, which may not suit domains where entity types serve fundamentally different functional
 284 roles (e.g. enzymes vs. substrates in biochemistry). We acknowledge this limitation: in functionally
 285 specialised domains, symmetry should receive lower weight or be replaced by a type-aware variant
 286 that measures within-type consistency rather than across-type uniformity. Similarly, contradicts
 287 edges need not represent noise—in scientific discourse, competing hypotheses are valuable and
 288 their explicit representation is a feature, not a defect. Our coherence penalty targets only *dense*
 289 contradiction (high contradicts-to-edge ratio), which signals structural noise; sparse contradiction is
 290 tolerated. Future work includes domain-adaptive weighting, where component weights are learned
 291 per domain via held-out validation performance.

292 **LLM dependence and safety.** The proposal quality depends on the LLM’s domain knowledge
 293 and instruction following. Our experiments use a single model (gpt-oss:20b); ensembling across
 294 model families could improve diversity and robustness. The island-model architecture naturally sup-
 295 ports heterogeneous LLM backends per island. To mitigate the risk of LLM-generated misinforma-
 296 tion entering scientific workflows, proposals enter a *staging layer*: they are scored by the Harmony
 297 metric and archived, but never automatically integrated into the base KG. Every proposal requires
 298 an explicit falsification condition, enabling principled rejection. Before any proposal is treated as
 299 established knowledge, it must pass expert review—our rubric gate (mean plausibility ≥ 3.0) serves
 300 as a minimum quality filter, and we recommend domain-expert validation as a mandatory step in
 301 any deployment.

302 **Scalability.** The Harmony framework’s computational cost is dominated by DistMult training
 303 ($O(|E| \cdot d \cdot \text{epochs})$) and LLM inference ($O(T_{\max} \cdot 4)$ calls for 4 islands). The three graph-structural
 304 components (compressibility, coherence, symmetry) are $O(|V| + |E|)$ each. For our current KGs
 305 (17–22 entities), total wall time is ~ 10 minutes per domain on a single CPU. Scaling to medium-
 306 size KGs (200–300 entities) increases DistMult training time linearly with $|E|$ but does not change
 307 the LLM call count, making the framework practical for KGs up to ~ 1000 entities without GPU
 308 hardware.

309 **Broader impacts.** This work aims to accelerate scientific theory discovery by automating the
 310 generation and evaluation of structural hypotheses in knowledge graphs. On the positive side, this
 311 could reduce the time researchers spend formulating initial hypotheses and help surface non-obvious
 312 connections across disciplinary boundaries. On the negative side, LLM-generated proposals can be
 313 plausible-sounding yet factually incorrect; deploying such proposals without expert validation risks
 314 propagating erroneous claims into downstream scientific workflows. We mitigate this by including

315 falsification conditions in every proposal and requiring expert rubric scoring before any claim is
316 treated as established.

317 **Limitations.** (i) The seven-relation type vocabulary, while sufficient for our five domains, may be
318 too coarse for highly specialised fields (e.g. organic chemistry reaction types). (ii) Expert rubric
319 evaluation is currently manual and limited to the top-5 proposals; automated plausibility scoring
320 (e.g. via literature retrieval) would improve scalability. (iii) The Harmony metric treats all edge
321 types equally in the compressibility and coherence components; domain-specific type hierarchies
322 could improve these signals. (iv) Results depend on a single random seed for dataset splitting; multi-
323 seed evaluation would strengthen statistical claims.

324 7 Conclusion

325 We presented Harmony, a framework for automated theory discovery in scientific knowledge graphs.
326 The four-component Harmony metric—compressibility, coherence, symmetry, and generativity—
327 provides a principled, domain-agnostic quality signal for scoring KG mutations. An LLM proposer
328 generates structured, falsifiable theory-level claims, which are validated and archived in a MAP-
329 Elites quality-diversity grid across an island-model search topology.

330 Calibration experiments confirm 31–65% improvements over frequency baselines on two domains.
331 Discovery experiments on astronomy, physics, and materials science KGs show consistent Hits@10
332 gains over a standalone DistMult baseline, with expert plausibility scores meeting the pre-registered
333 ≥ 3.0 threshold.

334 Future work includes scaling to larger scientific KGs (e.g. domain-specific subsets of Wikidata),
335 extending the relation type vocabulary, integrating literature-retrieval-based plausibility scoring, and
336 exploring multi-LLM ensembles across islands for improved diversity.

337 A Dataset Statistics

338 Table 4 summarises the five knowledge graph domains.

Table 4: Knowledge graph domain statistics. All KGs use the shared seven-relation type vocabulary.

Domain	Entities	Edges	Entity types	Primary relations
Linear algebra	17	45	5	derives, depends_on
Periodic table	22	58	4	maps_to, generalizes
Astronomy	20	52	6	explains, derives
Physics	18	48	5	derives, explains
Materials science	19	50	5	maps_to, depends_on

339 B Ablation Details

340 The ablation study (Table 2) uses the linear algebra KG with $n_{\text{bootstrap}} = 200$ samples. For each
341 ablation variant, one weight is set to zero and the remaining three are renormalised to sum to 1.
342 Bootstrap 95% confidence intervals are computed via the percentile method on the mean Harmony
343 score.

344 **Weight sensitivity.** We evaluate six weight configurations from the calibration gate grid ($\alpha \in$
345 $\{0.3, 0.5, 0.7\}$, $\beta \in \{0.1, 0.3\}$, $\gamma = \delta = 0.25$). All configurations show Harmony > frequency
346 baseline, with $\alpha = 0.5, \beta = 0.3$ yielding the highest mean Harmony score. This suggests that
347 a moderate compressibility weight combined with non-trivial coherence weight best captures the
348 structure of our curated KGs.

349 C Proposal Validation Rules

350 The deterministic validator enforces three rules:

- 351 1. **Text length:** `claim`, `justification`, and `falsification_condition` must each be
 352 ≥ 10 characters. `kg_domain` must be ≥ 3 characters (controlled vocabulary, not free text).
 353 2. **Type-specific fields:** `ADD_EDGE` requires `source_entity`, `target_entity`, and
 354 `edge_type`; `ADD_ENTITY` requires `entity_id` and `entity_type`; `REMOVE_EDGE` re-
 355 quires `source_entity`, `target_entity`, and `edge_type`; `REMOVE_ENTITY` requires
 356 `entity_id`.
 357 3. **Edge type validity:** `edge_type` must be one of the seven valid `EdgeType` names.

358 **D Full Proposal Examples**

359 Below are three complete proposal records from the astronomy archive, showing all fields including
 360 justification and falsification conditions.

361 **Proposal 1: Stellar nucleosynthesis → heavy element abundance.**

- 362 • **Type:** `ADD_EDGE`
 363 • **Source:** `stellar_nucleosynthesis`
 364 • **Target:** `heavy_element_abundance`
 365 • **Edge type:** `explains`
 366 • **Claim:** “Stellar nucleosynthesis explains the observed abundance pattern of heavy ele-
 367 ments in planetary nebulae.”
 368 • **Justification:** “The s-process and r-process nucleosynthesis pathways in AGB stars and su-
 369 pernovae produce characteristic abundance patterns that match spectroscopic observations
 370 of planetary nebulae.”
 371 • **Falsification:** “Discovery of heavy element abundance patterns in planetary nebulae incon-
 372 sistent with any known nucleosynthesis pathway would falsify this claim.”

373 **Proposal 2: Mass–luminosity relation derivation.**

- 374 • **Type:** `ADD_EDGE`
 375 • **Source:** `hydrostatic_equilibrium`
 376 • **Target:** `mass_luminosity_relation`
 377 • **Edge type:** `derives`
 378 • **Claim:** “The mass–luminosity relation derives from hydrostatic equilibrium in main se-
 379 quence stars.”
 380 • **Justification:** “Balancing gravitational pressure against radiation pressure in the stellar
 381 core, combined with opacity-dependent energy transport, yields $L \propto M^{3.5}$ for main se-
 382 quence stars.”
 383 • **Falsification:** “A main sequence star population where luminosity is uncorrelated with
 384 mass would disprove this derivation.”

385 **Proposal 3: Magnetar as new entity.**

- 386 • **Type:** `ADD_ENTITY`
 387 • **Entity ID:** `magnetar`
 388 • **Entity type:** `celestial_object`
 389 • **Claim:** “Magnetar generalises the neutron star category with extreme magnetic field prop-
 390 erties ($B > 10^{14}$ G).”
 391 • **Justification:** “Magnetars are observationally distinct from ordinary neutron stars due to
 392 their ultra-strong magnetic fields, which power soft gamma repeaters and anomalous X-ray
 393 pulsars.”
 394 • **Falsification:** “Evidence that magnetar-attributed emissions originate from non-magnetic
 395 mechanisms would undermine this classification.”

396 **E LLM Prompt Templates**

397 We include the exact prompt templates used for proposal generation. Both modes share a common
 398 preamble with KG statistics, strategy instruction, top proposals, and recent failures.

399 **Free mode (default).** The free-mode prompt shows a sample of up to 20 entity IDs from the KG
400 to ground the LLM without over-constraining it:

```
401     You are a theory-discovery agent for knowledge graph research.  
402     Knowledge Graph: domain='{}domain', entities={N}, edges={M}  
403     Strategy: {REFINEMENT|COMBINATION|NOVEL} -- {strategy description}  
404     Top proposals so far: {top 3 proposals or "None yet"}  
405     Recent validation failures: {up to 5 failure messages or "None"}  
406     EXAMPLE ENTITY IDs from this KG (showing K of N): {entity_1},  
407     {entity_2}, ...  
408     VALID EDGE TYPES: depends_on, derives, equivalent_to, maps_to,  
409     explains, contradicts, generalizes  
410     IMPORTANT: source_entity and target_entity MUST be exact entity IDs  
411     from this KG.  
412     Return ONLY a JSON object (no extra text) with fields: id,  
413     proposal_type, claim, justification, falsification_condition,  
414     kg_domain, source_entity, target_entity, edge_type, entity_id,  
415     entity_type
```

416 **Constrained mode (stagnation recovery).** When an island stagnates ($S = 5$ generations without
417 valid proposals), the prompt switches to constrained mode, which enumerates *all* valid entity IDs
418 and edge type names explicitly:

```
419     ... [same preamble] ...  
420     VALID ENTITY IDs (use EXACTLY as written): {all entity IDs}  
421     VALID EDGE TYPES (use EXACTLY as written): depends_on, derives,  
422     equivalent_to, maps_to, explains, contradicts, generalizes
```

423 F Proposal Failure Rate Statistics

424 Figure 2 shows the valid proposal rate converging to ≥ 0.50 by generation 10 across all discovery
425 domains. The initial failure rate (generations 1–3) is typically 60–80%, dominated by entity ground-
426 ing errors (referencing entities not in the KG). The entity sample in free-mode prompts (up to 20
427 entities) and the stagnation recovery mechanism (Section 3.4) together reduce failures to <30% by
428 generation 10. Constrained-mode prompts achieve $\geq 95\%$ validity but produce less diverse propos-
429 als.

430 G Code and Data Availability

431 Source code and all experimental artifacts are publicly available:

- 432 • **Code repository:** anonymised for review; will be released upon acceptance.
- 433 • **Data archive:** Zenodo (DOI: 10.5281/zenodo.18795697), containing all KG datasets,
434 checkpoints, and generated proposals.

435 H Hyperparameter Settings

436 Table 5 lists all hyperparameters used in the experiments.

437 **Compute resources.** All experiments were run on a single Apple M-series CPU (no GPU). Each
438 domain completes 20 generations in approximately 10 minutes of wall-clock time (including LLM
439 inference via locally served Ollama). The total compute for the three reported domains is under
440 30 CPU-minutes. Preliminary experiments during development required an additional ~ 2 hours of
441 CPU time.

Table 5: Hyperparameter settings.

Component	Parameter	Value
Harmony metric	α (compressibility)	0.25
	β (coherence)	0.25
	γ (symmetry)	0.25
	δ (generativity)	0.25
DistMult	Embedding dimension	50
	Training epochs	100
	Margin	1.0
	Learning rate	0.01
	Negative samples	5
	Mask ratio	0.20
Search loop	Islands	4
	Population per island	5
	Generations	20
	Migration interval	10
	Temperatures	{0.3, 0.3, 0.8, 1.2}
Stagnation	Trigger generations (S)	5
	Recovery generations (R)	3
MAP-Elites	Grid size	5×5
	Descriptors	simplicity, Harmony gain
Value function	λ (cost penalty)	0.1

489 **NeurIPS Paper Checklist**

490 **1. Claims**

491 Question: Do the main claims made in the abstract and introduction accurately reflect the
 492 paper’s contributions and scope?

493 Answer: **[Yes]**

494 Justification: The abstract and introduction state three contributions: (1) the Harmony met-
 495 ric (Section 3), (2) the island-model search loop (Section 3), and (3) LLM-guided proposal
 496 generation (Section 3). Section 5 validates each with quantitative results.

497 Guidelines:

- 498 • The answer NA means that the abstract and introduction do not include the claims
 499 made in the paper.
- 500 • The abstract and/or introduction should clearly state the claims made, including the
 501 contributions made in the paper and important assumptions and limitations. A No or
 502 NA answer to this question will not be perceived well by the reviewers.
- 503 • The claims made should match theoretical and experimental results, and reflect how
 504 much the results can be expected to generalize to other settings.
- 505 • It is fine to include aspirational goals as motivation as long as it is clear that these
 506 goals are not attained by the paper.

507 **2. Limitations**

508 Question: Does the paper discuss the limitations of the work performed by the authors?

509 Answer: **[Yes]**

510 Justification: Section 6 contains a dedicated “Limitations” paragraph addressing four spe-
 511 cific limitations: coarse relation vocabulary, manual expert rubric, equal edge-type weight-
 512 ing, and single-seed evaluation.

513 Guidelines:

- 514 • The answer NA means that the paper has no limitation while the answer No means
 515 that the paper has limitations, but those are not discussed in the paper.

- The authors are encouraged to create a separate "Limitations" section in their paper.
- The paper should point out any strong assumptions and how robust the results are to violations of these assumptions (e.g., independence assumptions, noiseless settings, model well-specification, asymptotic approximations only holding locally). The authors should reflect on how these assumptions might be violated in practice and what the implications would be.
- The authors should reflect on the scope of the claims made, e.g., if the approach was only tested on a few datasets or with a few runs. In general, empirical results often depend on implicit assumptions, which should be articulated.
- The authors should reflect on the factors that influence the performance of the approach. For example, a facial recognition algorithm may perform poorly when image resolution is low or images are taken in low lighting. Or a speech-to-text system might not be used reliably to provide closed captions for online lectures because it fails to handle technical jargon.
- The authors should discuss the computational efficiency of the proposed algorithms and how they scale with dataset size.
- If applicable, the authors should discuss possible limitations of their approach to address problems of privacy and fairness.
- While the authors might fear that complete honesty about limitations might be used by reviewers as grounds for rejection, a worse outcome might be that reviewers discover limitations that aren't acknowledged in the paper. The authors should use their best judgment and recognize that individual actions in favor of transparency play an important role in developing norms that preserve the integrity of the community. Reviewers will be specifically instructed to not penalize honesty concerning limitations.

3. Theory assumptions and proofs

Question: For each theoretical result, does the paper provide the full set of assumptions and a complete (and correct) proof?

Answer: [NA]

Justification: The paper does not claim formal theorems. The Harmony metric (Eqs. 1–6) is defined compositionally; all component definitions and normalisation conventions are stated explicitly in Section 3.

Guidelines:

- The answer NA means that the paper does not include theoretical results.
- All the theorems, formulas, and proofs in the paper should be numbered and cross-referenced.
- All assumptions should be clearly stated or referenced in the statement of any theorems.
- The proofs can either appear in the main paper or the supplemental material, but if they appear in the supplemental material, the authors are encouraged to provide a short proof sketch to provide intuition.
- Inversely, any informal proof provided in the core of the paper should be complemented by formal proofs provided in appendix or supplemental material.
- Theorems and Lemmas that the proof relies upon should be properly referenced.

4. Experimental result reproducibility

Question: Does the paper fully disclose all the information needed to reproduce the main experimental results of the paper to the extent that it affects the main claims and/or conclusions of the paper (regardless of whether the code and data are provided or not)?

Answer: [Yes]

Justification: Appendix H lists all hyperparameters; Appendix A provides dataset statistics; Section 4 describes the experimental protocol; a single fixed seed ($s = 42$) is used throughout.

Guidelines:

- The answer NA means that the paper does not include experiments.

- If the paper includes experiments, a No answer to this question will not be perceived well by the reviewers: Making the paper reproducible is important, regardless of whether the code and data are provided or not.
- If the contribution is a dataset and/or model, the authors should describe the steps taken to make their results reproducible or verifiable.
- Depending on the contribution, reproducibility can be accomplished in various ways. For example, if the contribution is a novel architecture, describing the architecture fully might suffice, or if the contribution is a specific model and empirical evaluation, it may be necessary to either make it possible for others to replicate the model with the same dataset, or provide access to the model. In general, releasing code and data is often one good way to accomplish this, but reproducibility can also be provided via detailed instructions for how to replicate the results, access to a hosted model (e.g., in the case of a large language model), releasing of a model checkpoint, or other means that are appropriate to the research performed.
- While NeurIPS does not require releasing code, the conference does require all submissions to provide some reasonable avenue for reproducibility, which may depend on the nature of the contribution. For example
 - (a) If the contribution is primarily a new algorithm, the paper should make it clear how to reproduce that algorithm.
 - (b) If the contribution is primarily a new model architecture, the paper should describe the architecture clearly and fully.
 - (c) If the contribution is a new model (e.g., a large language model), then there should either be a way to access this model for reproducing the results or a way to reproduce the model (e.g., with an open-source dataset or instructions for how to construct the dataset).
 - (d) We recognize that reproducibility may be tricky in some cases, in which case authors are welcome to describe the particular way they provide for reproducibility. In the case of closed-source models, it may be that access to the model is limited in some way (e.g., to registered users), but it should be possible for other researchers to have some path to reproducing or verifying the results.

5. Open access to data and code

Question: Does the paper provide open access to the data and code, with sufficient instructions to faithfully reproduce the main experimental results, as described in supplemental material?

Answer: [Yes]

Justification: At submission time, an anonymised repository and a Zenodo draft artifact record are provided to support reproducibility. Upon acceptance, these assets will be de-anonymised and released under an open-source licence with a citable DOI.

Guidelines:

- The answer NA means that paper does not include experiments requiring code.
- Please see the NeurIPS code and data submission guidelines (<https://nips.cc/public/guides/CodeSubmissionPolicy>) for more details.
- While we encourage the release of code and data, we understand that this might not be possible, so "No" is an acceptable answer. Papers cannot be rejected simply for not including code, unless this is central to the contribution (e.g., for a new open-source benchmark).
- The instructions should contain the exact command and environment needed to run to reproduce the results. See the NeurIPS code and data submission guidelines (<https://nips.cc/public/guides/CodeSubmissionPolicy>) for more details.
- The authors should provide instructions on data access and preparation, including how to access the raw data, preprocessed data, intermediate data, and generated data, etc.
- The authors should provide scripts to reproduce all experimental results for the new proposed method and baselines. If only a subset of experiments are reproducible, they should state which ones are omitted from the script and why.
- At submission time, to preserve anonymity, the authors should release anonymized versions (if applicable).

- 625 • Providing as much information as possible in supplemental material (appended to the
626 paper) is recommended, but including URLs to data and code is permitted.

627 **6. Experimental setting/details**

628 Question: Does the paper specify all the training and test details (e.g., data splits, hyper-
629 parameters, how they were chosen, type of optimizer, etc.) necessary to understand the
630 results?

631 Answer: [Yes]

632 Justification: Section 4 describes the experimental setup including baselines, evaluation
633 protocol, and dataset split ratios. Appendix H lists all hyperparameters. Appendix A pro-
634 vides dataset entity and edge count statistics.

635 Guidelines:

- 636 • The answer NA means that the paper does not include experiments.
637 • The experimental setting should be presented in the core of the paper to a level of
638 detail that is necessary to appreciate the results and make sense of them.
639 • The full details can be provided either with the code, in appendix, or as supplemental
640 material.

641 **7. Experiment statistical significance**

642 Question: Does the paper report error bars suitably and correctly defined or other appropri-
643 ate information about the statistical significance of the experiments?

644 Answer: [No]

645 Justification: The ablation study (Appendix B) reports bootstrap 95% CIs, but the main
646 results (Table 1) are single-seed without error bars. This limitation is explicitly acknowl-
647 edged in the Limitations paragraph of Section 6; multi-seed evaluation is noted as future
648 work.

649 Guidelines:

- 650 • The answer NA means that the paper does not include experiments.
651 • The authors should answer "Yes" if the results are accompanied by error bars, confi-
652 dence intervals, or statistical significance tests, at least for the experiments that support
653 the main claims of the paper.
654 • The factors of variability that the error bars are capturing should be clearly stated (for
655 example, train/test split, initialization, random drawing of some parameter, or overall
656 run with given experimental conditions).
657 • The method for calculating the error bars should be explained (closed form formula,
658 call to a library function, bootstrap, etc.).
659 • The assumptions made should be given (e.g., Normally distributed errors).
660 • It should be clear whether the error bar is the standard deviation or the standard error
661 of the mean.
662 • It is OK to report 1-sigma error bars, but one should state it. The authors should prefer-
663 ably report a 2-sigma error bar than state that they have a 96% CI, if the hypothesis of
664 Normality of errors is not verified.
665 • For asymmetric distributions, the authors should be careful not to show in tables or
666 figures symmetric error bars that would yield results that are out of range (e.g. negative
667 error rates).
668 • If error bars are reported in tables or plots, The authors should explain in the text how
669 they were calculated and reference the corresponding figures or tables in the text.

670 **8. Experiments compute resources**

671 Question: For each experiment, does the paper provide sufficient information on the com-
672 puter resources (type of compute workers, memory, time of execution) needed to reproduce
673 the experiments?

674 Answer: [Yes]

675 Justification: Appendix H reports the hardware (CPU-only, Apple M-series) and wall-clock
676 time (approximately 10 minutes per domain for 20 generations). No GPU resources were
677 used.

678 Guidelines:

- The answer NA means that the paper does not include experiments.
- The paper should indicate the type of compute workers CPU or GPU, internal cluster, or cloud provider, including relevant memory and storage.
- The paper should provide the amount of compute required for each of the individual experimental runs as well as estimate the total compute.
- The paper should disclose whether the full research project required more compute than the experiments reported in the paper (e.g., preliminary or failed experiments that didn't make it into the paper).

687 **9. Code of ethics**

688 Question: Does the research conducted in the paper conform, in every respect, with the
689 NeurIPS Code of Ethics <https://neurips.cc/public/EthicsGuidelines>?

690 Answer: [Yes]

691 Justification: No human subjects were involved. All knowledge graphs are curated from
692 publicly available academic sources. No personally identifiable or scraped data is used.

693 Guidelines:

- The answer NA means that the authors have not reviewed the NeurIPS Code of Ethics.
- If the authors answer No, they should explain the special circumstances that require a deviation from the Code of Ethics.
- The authors should make sure to preserve anonymity (e.g., if there is a special consideration due to laws or regulations in their jurisdiction).

694 **10. Broader impacts**

700 Question: Does the paper discuss both potential positive societal impacts and negative
701 societal impacts of the work performed?

702 Answer: [Yes]

703 Justification: Section 6 includes a “Broader impacts” paragraph discussing positive impacts
704 (accelerating scientific theory discovery) and negative risks (LLM-generated claims
705 may be plausible-sounding but factually incorrect, requiring expert validation before use in
706 downstream scientific workflows).

707 Guidelines:

- The answer NA means that there is no societal impact of the work performed.
- If the authors answer NA or No, they should explain why their work has no societal impact or why the paper does not address societal impact.
- Examples of negative societal impacts include potential malicious or unintended uses (e.g., disinformation, generating fake profiles, surveillance), fairness considerations (e.g., deployment of technologies that could make decisions that unfairly impact specific groups), privacy considerations, and security considerations.
- The conference expects that many papers will be foundational research and not tied to particular applications, let alone deployments. However, if there is a direct path to any negative applications, the authors should point it out. For example, it is legitimate to point out that an improvement in the quality of generative models could be used to generate deepfakes for disinformation. On the other hand, it is not needed to point out that a generic algorithm for optimizing neural networks could enable people to train models that generate Deepfakes faster.
- The authors should consider possible harms that could arise when the technology is being used as intended and functioning correctly, harms that could arise when the technology is being used as intended but gives incorrect results, and harms following from (intentional or unintentional) misuse of the technology.
- If there are negative societal impacts, the authors could also discuss possible mitigation strategies (e.g., gated release of models, providing defenses in addition to attacks, mechanisms for monitoring misuse, mechanisms to monitor how a system learns from feedback over time, improving the efficiency and accessibility of ML).

730 **11. Safeguards**

731 Question: Does the paper describe safeguards that have been put in place for responsible
732 release of data or models that have a high risk for misuse (e.g., pretrained language models,
733 image generators, or scraped datasets)?

734 Answer: [NA]

735 Justification: The paper does not release pretrained models or scraped datasets. The re-
736 leased assets are small curated knowledge graphs and search-loop code, which pose no
737 misuse risk.

738 Guidelines:

- 739 • The answer NA means that the paper poses no such risks.
- 740 • Released models that have a high risk for misuse or dual-use should be released with
741 necessary safeguards to allow for controlled use of the model, for example by re-
742 quiring that users adhere to usage guidelines or restrictions to access the model or
743 implementing safety filters.
- 744 • Datasets that have been scraped from the Internet could pose safety risks. The authors
745 should describe how they avoided releasing unsafe images.
- 746 • We recognize that providing effective safeguards is challenging, and many papers do
747 not require this, but we encourage authors to take this into account and make a best
748 faith effort.

749 12. Licenses for existing assets

750 Question: Are the creators or original owners of assets (e.g., code, data, models), used in
751 the paper, properly credited and are the license and terms of use explicitly mentioned and
752 properly respected?

753 Answer: [Yes]

754 Justification: DistMult [14] and TransE [2] are cited. Core Python libraries (NumPy, scikit-
755 learn) are BSD-3-Clause licensed. Knowledge graphs are original curated datasets.

756 Guidelines:

- 757 • The answer NA means that the paper does not use existing assets.
- 758 • The authors should cite the original paper that produced the code package or dataset.
- 759 • The authors should state which version of the asset is used and, if possible, include a
760 URL.
- 761 • The name of the license (e.g., CC-BY 4.0) should be included for each asset.
- 762 • For scraped data from a particular source (e.g., website), the copyright and terms of
763 service of that source should be provided.
- 764 • If assets are released, the license, copyright information, and terms of use in the pack-
765 age should be provided. For popular datasets, paperswithcode.com/datasets has
766 curated licenses for some datasets. Their licensing guide can help determine the li-
767 cense of a dataset.
- 768 • For existing datasets that are re-packaged, both the original license and the license of
769 the derived asset (if it has changed) should be provided.
- 770 • If this information is not available online, the authors are encouraged to reach out to
771 the asset's creators.

772 13. New assets

773 Question: Are new assets introduced in the paper well documented and is the documenta-
774 tion provided alongside the assets?

775 Answer: [Yes]

776 Justification: Five curated KG datasets are documented in Appendix A with entity/edge
777 counts, type vocabularies, and split ratios. The proposal schema is defined in Section 3
778 with validation rules in Appendix C.

779 Guidelines:

- 780 • The answer NA means that the paper does not release new assets.

- 781 • Researchers should communicate the details of the dataset/code/model as part of their
782 submissions via structured templates. This includes details about training, license,
783 limitations, etc.
784 • The paper should discuss whether and how consent was obtained from people whose
785 asset is used.
786 • At submission time, remember to anonymize your assets (if applicable). You can
787 either create an anonymized URL or include an anonymized zip file.

788 **14. Crowdsourcing and research with human subjects**

789 Question: For crowdsourcing experiments and research with human subjects, does the pa-
790 per include the full text of instructions given to participants and screenshots, if applicable,
791 as well as details about compensation (if any)?

792 Answer: [NA]

793 Justification: No crowdsourcing or research with human subjects was conducted.

794 Guidelines:

- 795 • The answer NA means that the paper does not involve crowdsourcing nor research
796 with human subjects.
797 • Including this information in the supplemental material is fine, but if the main contri-
798 bution of the paper involves human subjects, then as much detail as possible should
799 be included in the main paper.
800 • According to the NeurIPS Code of Ethics, workers involved in data collection, cura-
801 tion, or other labor should be paid at least the minimum wage in the country of the
802 data collector.

803 **15. Institutional review board (IRB) approvals or equivalent for research with human
804 subjects**

805 Question: Does the paper describe potential risks incurred by study participants, whether
806 such risks were disclosed to the subjects, and whether Institutional Review Board (IRB)
807 approvals (or an equivalent approval/review based on the requirements of your country or
808 institution) were obtained?

809 Answer: [NA]

810 Justification: No human subjects research was conducted; IRB approval is not applicable.

811 Guidelines:

- 812 • The answer NA means that the paper does not involve crowdsourcing nor research
813 with human subjects.
814 • Depending on the country in which research is conducted, IRB approval (or equiva-
815 lent) may be required for any human subjects research. If you obtained IRB approval,
816 you should clearly state this in the paper.
817 • We recognize that the procedures for this may vary significantly between institutions
818 and locations, and we expect authors to adhere to the NeurIPS Code of Ethics and the
819 guidelines for their institution.
820 • For initial submissions, do not include any information that would break anonymity
821 (if applicable), such as the institution conducting the review.

822 **16. Declaration of LLM usage**

823 Question: Does the paper describe the usage of LLMs if it is an important, original, or
824 non-standard component of the core methods in this research? Note that if the LLM is used
825 only for writing, editing, or formatting purposes and does not impact the core methodology,
826 scientific rigorousness, or originality of the research, declaration is not required.

827 Answer: [Yes]

828 Justification: LLM-based proposal generation is a core methodological component de-
829 scribed in Section 3. The specific model family (local Ollama-served model) and prompting
830 strategy (entity-grounded, four-phase rotation: refine, combine, refine, novel) are detailed
831 in Sections 3 and 4.

832 Guidelines:

- 833 • The answer NA means that the core method development in this research does not
834 involve LLMs as any important, original, or non-standard components.
835 • Please refer to our LLM policy (<https://neurips.cc/Conferences/2025/LLM>)
836 for what should or should not be described.
